PROVISIONAL SPECIFICATION

Invention Title: "ATTACHABLE SENSOR FOR PUTTING STROKE PATH AND PLANE DETECTION"

The invention is described in the following statement:

ATTACHABLE SENSOR FOR PUTTING STROKE PATH AND PLANE DETECTION

This invention relates to a device for detecting inaccuracies in a putting stroke for the game of golf. In particular, this invention relates to a sensor that detects imperfections in smoothness of stroke, path of the putter head and face angle of the club head during a putting stoke.

BACKGROUND

The game of golf is one of the largest recreational sports in the world in terms of participants. Golf requires consistent precision of movement to achieve mastery of the game. Subtle imperfections in the execution of strokes produce amplified errors in the outcome of the shot.

Being able to putt in a technically correct manner is of vital importance to all golfers from the high handicap, weekend club player to the professional as this is where most strokes are dropped during a round. This is acknowledged in one of the most commonly used phrases on the golf course, "drive for show, putt for dough". It is also one of the hardest aspects of the game to master. There are four main technical inaccuracies that are common among players that cause inconsistent swing and hence missed putts.

1. Professionals cite rotation of the wrists during back swing, the transition from back swing to forward swing or forward swing resulting in rotation of the club in a direction axial to the vertical axis as the primary reason for inaccurate putting strokes. The club head should remain perpendicular to the intended line of travel of the ball during the backstroke.
2. Another reason for inaccurate putting is due to deviation of the club head from the intended line of the putt. The putter should trace a straight line from the start of the back swing, through to the transition from back swing to forward swing and back

through the forward swing to contact with the ball.

3. A further reason cited for inaccurate putts is due to accelerating too quickly during back swing and/or forward swing. Ideally, smooth acceleration and deceleration should be achieved at all times during back swing, forward swing and the transition between the two.
4. Rotation of the club head in a direction axial to the intended line of travel of the ball is a further technical inaccuracy in player's putting strokes. The club head should remain approximately parallel with the horizontal plane at all times during the stroke.

Most players generally seek the services of a professional to detect inaccuracies in their putting stroke and to correct them. The player then needs to practice these corrected putting techniques and implement the advice received through repetitive practice. Not only is this method of putting swing correction expensive, it is also often ineffective. When the player is practising the correct stroke, without supervision from their coach, bad habits tend to creep back into their action and the player spends their time practicing a technically incorrect stroke.

A more convenient and cost effective solution is for the player to use a device that monitors their stroke during practice and alert them when a stroke is technically inaccurate. In this way, a player can repetitively practice a correct stroke and mirror it during a game.

There is a large body of prior art that attempts to address this problem. US 4930787, in the name of Nobles, discloses a device for attachment to a putter which produces a signal during a putting stroke if the longitudinal axis of the putter head is rotated out of parallel with the horizon or when the putter head undergoes any clockwise or counter clockwise rotation on the backstroke.

This putting trainer is designed to be fixed, by means of screws or other fastening means, to the backside of the putter. Hence, a player using this device requires a special training putter to fix the device. It is probable

that this putter would have different weight and balance characteristics to the putter the golfer would use during a game. It should be appreciated that it is of greater benefit to practice with a putter that will be used during a game and hence this embodiment does not effectively address the problems listed above. This device uses two mercury bulbs for detecting rotation of the putter head in a direction axial to the intended line of travel of the ball.

The device does not address the path deviation problem, as mentioned in 2 above. Thus, the club head can trace any path during the back swing and no stroke error will be indicated. Hence, the device disclosed in US 4930787, is deficient in solving all of the problems of putting stroke inaccuracies as discussed above.

US 5435561, in the name of Conley, discloses and claims a putting stroke training device comprising an inertial sensor for detecting movement in a direction parallel to the plane of the club face and rotation of the club head in a direction axial to the longitudinal axis of the shaft during putting. The sensor includes an elongated arm mounted on a pivot point which is orientated in a direction perpendicular both to the longitudinal axis of the shaft of the club and also to the plane of the club face.

The design of this device necessitates the fact that it must be installed within the shaft of a putter. This is an obvious deficiency of this device as again, a player must practice with one club with the device installed and play with a separate club. Hence, as the practice club and playing club will no doubt have different balance points and characteristics, the benefits of putting practice using this device and a practice putter are lost.

US 5441269, in the name of Henwood, discloses a putting stroke training device that detects when the putter head has accelerated or decelerated too quickly, as in 3 above, and also when the putter head is rotated axially around the vertical axis at the moment of contact between the ball and the club head. This device uses a pendulum actuator and an impact actuator to sense technical faults in the putting stroke.

This device does not adequately address the problems of stroke inaccuracy as it only measures axial rotation of the club head around the

vertical at the moment of contact: Hence, a player may execute a stroke that causes the club to rotate axially around the vertical during back swing, but may correct this inaccuracy during forward swing to contact. This would not be considered a technically correct stroke but the device disclosed in this specification gives no indication to the player of the stroke error.

Furthermore, this device must either be installed within a cavity in a hollow club head, or secured on top of a club head by means of screws or similar fastening devices. Hence, again it is required to practice putting strokes using a putter that would not be used during play. There is minimal benefit in practicing with a putter with different characteristics to that of the putter used during a game.

Hence, there remains the need for a device for detecting inaccuracies in putting strokes such as those listed above. Furthermore, this device must be capable of being easily attached and unattached to a player's putter so that the same club can be used by a player in practice and in games. The advantage of such a device is that a player can detect and correct technical inaccuracies in their putting stroke and play a round of golf using the same club that has been used to practice shots correctly.

OBJECTIVE OF THE INVENTION

The object of the putting training device of the current invention is to solve one or more of the technical inaccuracies of golfers putting strokes as defined in the background statement. A further object of the invention is to provide a useful alternative to the known prior art.

DISCLOSURE OF THE INVENTION

In one form, although it need not be the only or indeed the broadest form, the invention resides in a putting trainer device comprising:

detection means including one or more tracks and a free moving component on each track biased to a neutral position; and

indicator means for indicating when said free moving component moves to an active position.

Appropriately, said track is a guided ramp inclined from said neutral position to end of said neutral position.

Appropriately, said putting trainer device has means for attachment to and removal from a putter club without any alterations to said putter being necessary.

Said attachment means may take the form of crescent shaped clip attachment.

Said free moving component may be a free rolling disc magnet and movement of said free rolling disc magnet to said active position is detected by means of a magnetic reed switch.

Alternately, said free moving component may be a free rolling ball bearing and detection of movement of said free rolling ball bearing to said active position is by means of contact with an electrical conductor on said track distal from said neutral position.

Appropriately, said detection means and said indication means are connected by means of an electrical circuit and detection causes said electrical circuit to complete thus initiating said indication means.

Said indication means may be an audible indication.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG 1 Isometric view of putting trainer device.

FIG 2 Component view of putting trainer device.

FIG 3 Component view of putting trainer device.

FIG 4 Top view of bottom housing section.

FIG 5 Schematic of circuit employed within putting training device.

DETAILED DESCRIPTION OF THE INVENTION

The present invention resides in a device for detecting inaccuracies in a putting stroke for the game of golf. In particular, this invention relates to a device that detects imperfections in smoothness of stroke, path of the putter head and face angle of the club head during a putting stoke. The device comprises a means for detecting stroke imperfections and a means for indicating when a stroke imperfection has been detected. The putting training device is attached to the shaft of the putter just above the putting head by the means of attachment discussed below. Throughout this description, like numerals are used to refer to the same elements of the invention shown in multiple figures.

One embodiment of the present invention is described below with reference to Figures 1 to 5. Where appropriate, a figure which bests shows the aspect under discussion is referred to. Where no figure is directly referred to it can be inferred that this aspect is present in multiple figures.

In reference to FIG 1, FIG 2, FIG 3 and FIG4, one embodiment of the putting trainer device 1 is shown. This embodiment of the present invention has a crescent shaped clip attachment means 2 for fixing the putter training device to the shaft of a putter. The attachment means 2 is connected to the detection and indication housing component 3 by a pivot 4. Pivot 4 is capable of vertical movement of the housing component relative to the attachment means and also rotation in a direction axial to the longitudinal axis of the putter head when attached to a putter shaft.

The housing component 3 is triangularly shaped with rounded vertices. The housing component 3 comprises two interlocking sections, top 5 and bottom 6, fastened by an appropriate means, in this case being a screw 7 through screw hole 8 in bottom section 5 and terminating inside threaded elongated cavity 9 of protruding elongated section 10 which is integrally formed in top interlocking section 5.

The bottom interlocking section 6 further comprises power switch (not shown), protruding pendulum cavity 12 integrally formed with section 6,

battery contact 13, protruding speaker cavity (not shown) integrally formed with section 6 and guided ramp adjustment screws, 14A and 14B. The top interlocking section 5 further comprises a levelling pendulum 15, two clear protruding observation components, 16A and 16B, and a clear protruding pendulum observation component 17.

Pivot 4 is used in conjunction with levelling pendulum 15 and pendulum observation component 17 to level the putting device in the horizontal plane. As many putting shafts are not exactly vertical, this feature ensures that the putting trainer of the present invention is substantially parallel with the longitudinal axis putter head in the horizontal plane.

The bottom interlocking housing section 6 is shown. This section contains printed circuit board 18, speaker 26, guided ramps, 19A and 19B, and one free moving component located between the guards on each ramp, in this embodiment being the free rolling disc magnets, 20A and 20B. Guided ramps 19A and 19B are fixed at an angle that is at 45 degrees to the longitudinal axis of the putter club head in the horizontal plane and are substantially perpendicular to each other < check this with Brian >.

The guided ramps, 19A and 19B, have elongated threaded cavities, 22A and 22B, in which guided ramp adjustment screws, 14A and 14B, terminate. Elongated threaded cavities, 22A and 22B, are formed within guided ramps, 19A and 19B, distal from disc magnet neutral positions 23A and 23B respectively. Guided ramp attachment screws, 24A and 24B, are located within guided ramps, 19A and 19B, distal from disc magnet neutral positions 23A and 23B respectively.

Guided ramps 19A and 19B are inclined from disc magnet neutral positions 23A and 23B to disc magnet active positions 11A and 11B located on guided ramps 19A and 19B distal from disc magnet neutral positions. The angle of this incline is altered by the tightening or loosening of guided ramp adjustment screws 24A and 24B. The movement of free rolling disc magnets 20A and 20B from disc magnet neutral positions 23A and 23B in a direction along guided ramps 19A and 19B to disc magnet active positions 11A and 11B is detected by magnetic reed switches 25A and 25B located on

printed circuit board 18.

The magnetic reed switches 25A and 25B are aligned substantially parallel to the longitudinal axis of guided ramps 19A and 19B and positioned distal to disc magnet neutral positions 23A and 23B respectively. These switches are always open, meaning that no circuit is complete. Upon detection of a repulsive magnetic force the switches close and the circuit shown in FIG 5 is completed. A person skilled in the art will be able to determine that when the circuit is completed, either by closing reed switch 25A and/or by closing reed switch 25B, the alarm will sound as these switches are in parallel.

Furthermore, a person skilled in the art will appreciate that the free rolling disc magnets 20A and 20B will not cause magnetic reed switches 25A and 25B to close when these magnets are positioned in disc magnet neutral positions 23A and 23B. This is due to the nature of a magnetic field around a disc and the strength of the magnetic force associated with this disc.

Upon detection of movement of disc magnets 20A and 20B away from disc magnet neutral positions 23A and 23B to disc magnet active positions 11A and 11B by magnetic reed switches 25A and 25B an indication is given of this occurrence providing that power switch, not shown, is in the ON position and that the there is an appropriate power source connected to the electrical circuit of printed circuit board 18 by means of a battery inserted in battery contact 13. This indication means may be visual, audible or tactile. In this embodiment of the putting training device, indication is given by means of a digital speaker 26 as shown in the schematic of FIG 5. When either or both magnetic reed switches 25A and 25B are closed the circuit is complete and an electrical signal is propagated to the speaker 26 causing a sound to be created.

Detection of movement of the magnetic discs along the guided ramps is the primary mechanism for detection of technical inaccuracies in a putting stroke. The putting training device of the present invention detects the four technical inaccuracies as discussed in the background section.

It will be appreciated that as the putting training device is located on

the putter shaft just above the club head that the movement of the putting trainer device closely mimics the movement of the club head. Hence, it is implied throughout the rest of this discussion that the device of the present invention mimics the movement of the putter head.

Rotation of the wrists during the back swing, forward swing or transition between the two produces rotation of the putter club head in a direction axial to the vertical axis. This rotation imparts a rotational force on the putting trainer device.

Consider if, during the back swing, the club head is rotated gently axially around the vertical axis such that the club head rotates in a clockwise direction from a top perspective. At the exact moment of transition from back swing to forward swing the velocity of the club head is zero as the force applied to the club head by the player through the shaft has changed from back swing to forward swing. In this case, the angle of guided ramp 19A has reduced in relation to the line of intended travel of the ball. At the transition stroke momentum is imparted on the free moving disc magnet. A perfect stroke would result in no movement of the free disc magnet as the resistance provided by the guards of guided ramp 19A and the inclination of the slope of this ramp would provided enough resistance to counter this force. In the rotational situation described above, the guided ramp 19A is aligned in a direction closer to the line of intended path of travel of the golf ball. In this situation the resistance offered by the walls of the guided ramp 19A is less as the effective line of force has changed due to the rotation of the club head. If this rotation is great enough the momentum force imparted on the free rolling disc magnet 20A will be enough to overcome the resistance offered by the walls and the slope of the guided ramp 19A and the free rolling disc magnet 20A will move away from the disc magnet neutral position 23A, to disc magnet active position 11A, and will close magnetic reed switch 25A causing an indication of swing error to be communicated to the golfer.

Similar mechanics of motion apply to all axial movement around the vertical axis for the putting training device and hence detection of all axial

motion is possible using the same principles as described above.

As discussed in the background section, deviation perpendicular to the intended line of travel of the ball is another technical flaw in golfers putting strokes. For example, consider that, during a back swing the putter head deviates perpendicularly from the intended line of travel of the golf ball in a direction way from the player putting. A perfect stroke would only have forces acting in the direction of the intended line of travel of the golf ball and, as discussed, this force is not sufficient to move the free rolling disc magnets 20A and 20B from their neutral positions 23A and 23B to their active positions 11A and 11B. In the deviation situation of above, a momentum force is applied in a direction perpendicular to the intended line of travel of the golf ball at the transition stroke. If this force is large enough to overcome the frictional forces of guided ramp 19A and the gravitational force imparted by the slope of guided ramp 19A then free rolling disc magnet 20A will move away from the disc magnet neutral position 23A, to disc magnet active position 11A, and will close magnetic reed switch 25A.

Similar principles apply to movement of the club head perpendicular to the line of intended travel of the golf ball in the direction of the player making the putt.

As discussed in the background section, players can miss putts because they tend to accelerate and decelerate the club head too erratically during the stroke. The putter training device of the current invention is capable of detecting when a player's stroke is not smooth enough.

A person skilled in the art would appreciate the fact that a body under acceleration has a force associated with it, the magnitude of which depends on its mass and level of acceleration. If the acceleration or deceleration of the putter head is excessive, the momentum force imparted on the free rolling disc magnets 20A and 20B will be great enough to overcome the resistive forces of the guided ramps 19A and 19B and the gravitational force applied by the slopes of the guided ramps on the free moving disc magnets. Hence, the free rolling disc magnets 20A and 20B will move away from the disc magnet neutral positions 23A and 23B, to disc magnet active positions

11A and 11B, and will close magnetic reed switches 25A and 25B.

Depending on the direction of the acceleration and deceleration either free rolling disc magnet 20A will move, free rolling disc magnet 20B will move or both will move causing the corresponding reed switches to close and thus initiating the indication means.

A further technical defect that is present in golf player's putting strokes is that they tend to rotate the club head in an axial direction around the line of the intended path of the golf ball. In this regard, a perfect stroke would have zero rotation of the longitudinal axis of the putter club head around the line of the intended path of the ball.

The golf putting trainer of the present invention is able to detect any rotation of this type and indicate it's occurrence to the player. For example, consider the situation when a putter is rotated axially to the line of the intended path of travel of the ball in a direction so that that end of the putter head distal from the shaft is lower than the end proximal to the shaft. In this situation, if the angle of rotation is great enough, free rolling disc magnet 20A will move away from disc magnet neutral position 23A, to disc magnet active position 11A, as the disc magnet overcomes the resistive forces of guided ramp 19A and the slope of this ramp is diminished due to this rotation. Hence, magnetic reed switch 25A will close and thus initiating the indication means. A similar result will occur for disc magnet 20B if rotation occurs in the other axial direction.

A person skilled in the art will appreciate that a combination of one or more of the motions discussed above will not impede the accurate detection and indication of technical inaccuracies in a putting stroke by the putting trainer device of the present invention.

As previously mentioned, the sensitivity of the golf putting trainer 1 can be altered. This is an advantage as the device caters for all levels of golfers, from the weekend player to the professional. Furthermore, the device can be altered to increase the sensitivity as the player's putting technique improves.

It will be appreciated by a person skilled in the art that the free moving

disc magnet and magnetic reed switches are not the only means of detection for the present invention. Using the same principles described above it is possible to replace the disc magnets with ball bearings which, upon contact with the end of the guided ramps, distal to the neutral position, an electrical circuit can be created to initiate the indication means.

Throughout the specification the aim has been to describe the preferred embodiments of the invention without limiting the invention to any one embodiment or specific collection of features.
